

Knowledge Organiser – Year 8 Space

Key words

Term	Definition
Day	The time it takes for a planet to rotate once on it's axis. Different planets have different days. On Earth this is 24 hours.
moon	A satellite of the Earth that takes about 28 days to orbit.
Orbit	The pathway of an object around another.
year	The time taken for a planet to travel around the sun, on Earth this is 365.24 days.
star	Typically at the centre of a Solar System containing the majority of the mass. Nuclear fusion takes place here creating elements heavier than Helium.
comet	Balls of ice and dust that have a very elliptical orbit around the sun.
asteroid	Rocks that orbit the sun, many can be found in the asteroid belt between Mars and Jupiter.
Dwarf planet	Neither a planet or a natural satellite it is in orbit of the sun with gravity strong enough to cause it to be a sphere however is has not cleared it's neighbours of other materials around it's orbit.
reflection	When light from a luminous objects bounces back off another object.
refraction	When light enters different densities of material it appears to 'bend'.

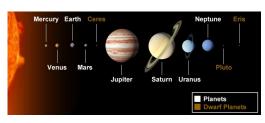

Satellites, orbits and gravity

A satellite is an object that has is in orbit. Natural satellites such as the Earth and the Moon or artificial satellites placed into orbit. There are many uses for artificial satellites such as TV, communication, monitoring the environment and spying on different countries.

Objects in orbit are said to always be 'falling' towards the earth due to gravity.

The Gravity of a planet or star depends on it's mass. The greater the mass the stronger the gravitational field. On Jupiter gravity is more than twice that of Earth, on the moon gravity is one fifth of that on Earth, imagine what it would be like to walk on each one!

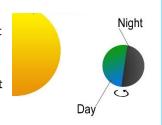

The Solar System and beyond

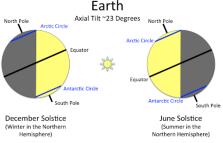

Our **Solar System** is one of billions in the galaxy and there are billions of galaxies in the **Universe**. Despite no evidence, scientists believe there is alien life out there! The main component of the Solar System is the Sun. The Sun is our nearest star and is almost 1.4 million kilometres in diameter. It contains 99.86 percent of the System's known mass and its gravity keeps all 8 planets, dwarf planets (due to size/orbit) asteroids and comets in orbit.

Day, Night, Seasons and Years

We have day and night because the Earth rotates. It spins on its axis, which is an imaginary line passing through the North and South Poles. The Earth spins slowly all the time, but we don't feel any movement because it turns smoothly and at the same speed.

The Earth's axis is tilted by 23.5°. When the axis points towards the sun, it is summer for that hemisphere, this is because the radiation from the sun in more concentrated on the Northern hemisphere. When the earth's axis points away, winter can be expected for the opposite reason.

A year is the time it takes for a planet to orbit the sun. The closer a planet to the sun the shorter its route and the greater the gravitational pull, typically these planets have sorter years. On Earth a year is 365.24 days, every four years we have a leap year adding an extra day to the calendar to keep it in sync.

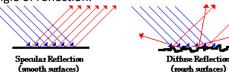

The moon

The shape of the moon is always the same however the sunlit piece we see from Earth changes with different perspective. The moon rotates once every 28 days so we only ever see the same side of the moon.

Reflection

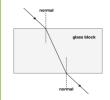

The angle of incidence is always equal to the angle of reflection.

When light reflects from a smooth surface we see a clear reflected image like a mirror. When the object is rough we see scattered light like in bike reflectors.

Refraction and lenses

Telescopes use refraction to look at distant stars. Refraction is when light slows at is passes from a more dense to a less dense object

In this case the light bends towards the normal. When the light leaves the block it moves away from the normal.

Telescopes use lenses to focus light onto a point.
